

Week1 Memo by Valentine Kerubo

Subject: Automating Operational Efficiency Tracking

Purpose

This memo explains a simple operational performance tracking tool that was developed to measure how efficiently different operational sites are performing. The tool compares each site's actual production or output with its planned target and assigns a performance status to help managers quickly understand which locations are meeting expectations and which require attention.

Why We Need to Automate Efficiency Tracking

Monitoring operational efficiency is an important part of managing performance. When this process is completed manually, staff must calculate percentages, compare results against performance standards, and identify underperforming sites one by one. This approach is time consuming and increases the possibility of calculation errors or inconsistent reporting.

By automating these calculations, performance information can be produced quickly and consistently. Managers receive the same evaluation every time the data is entered, allowing them to spend more time making decisions rather than preparing reports.

What the Tool Does

The tool accepts two pieces of information for each operational site: the actual output achieved and the planned target output. It then calculates an efficiency percentage that shows how closely each site met its target.

After calculating the percentage, the tool assigns one of three performance levels:

Normal: The site achieved at least 90% of its target.

Warning: The site achieved between 70% and 89% of its target.

Critical: The site achieved less than 70% of its target.

Finally, the tool produces a clear report showing each site's name, efficiency percentage, and performance status.

How This Helps Identify Problems Faster

Instead of reviewing numbers manually, managers can immediately see which sites require attention. Locations marked as Critical can be prioritized for investigation, while those marked as Warning can be monitored before their performance declines further.

This approach improves decision-making by providing a consistent and immediate summary of operational performance. It also makes it easier to compare multiple sites at the same time and identify trends that might otherwise be overlooked.

Recommendation

I recommend deploying this tool within the operations department as part of the daily or weekly performance reporting process. Supervisors could enter each site's production figures at the end of every reporting period, and the tool would automatically generate an updated performance report. As the department grows, the same approach can be expanded to include additional operational sites and other key performance measures. This would provide management with faster, more reliable information and support timely decisions that improve operational efficiency.
